

Quarterly Performance Analysis

The following report summarizes measured throughput across the last four quarters. Each data point was sampled from the production cluster under sustained load, and error bars reflect one standard deviation.

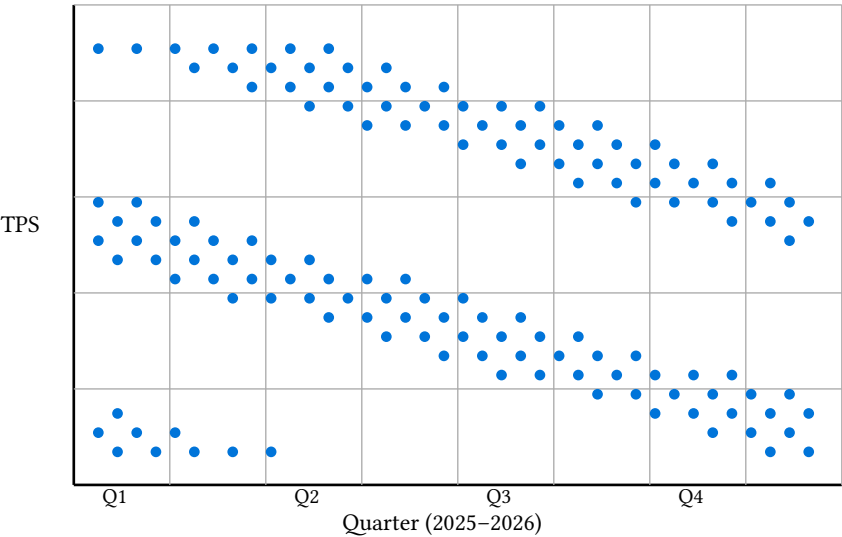

Figure 1: Scatter of throughput samples across quarters.

Throughput grew steadily through the year, with the largest jump occurring between the second and third quarters after the caching layer was rewritten. The regression visible in early Q4 corresponds to the incident window documented in the operations log.

Overall, the cluster ended the year at roughly twice its starting capacity, and the tail latency distribution narrowed considerably.
